Riparian Summit, Davis, CA

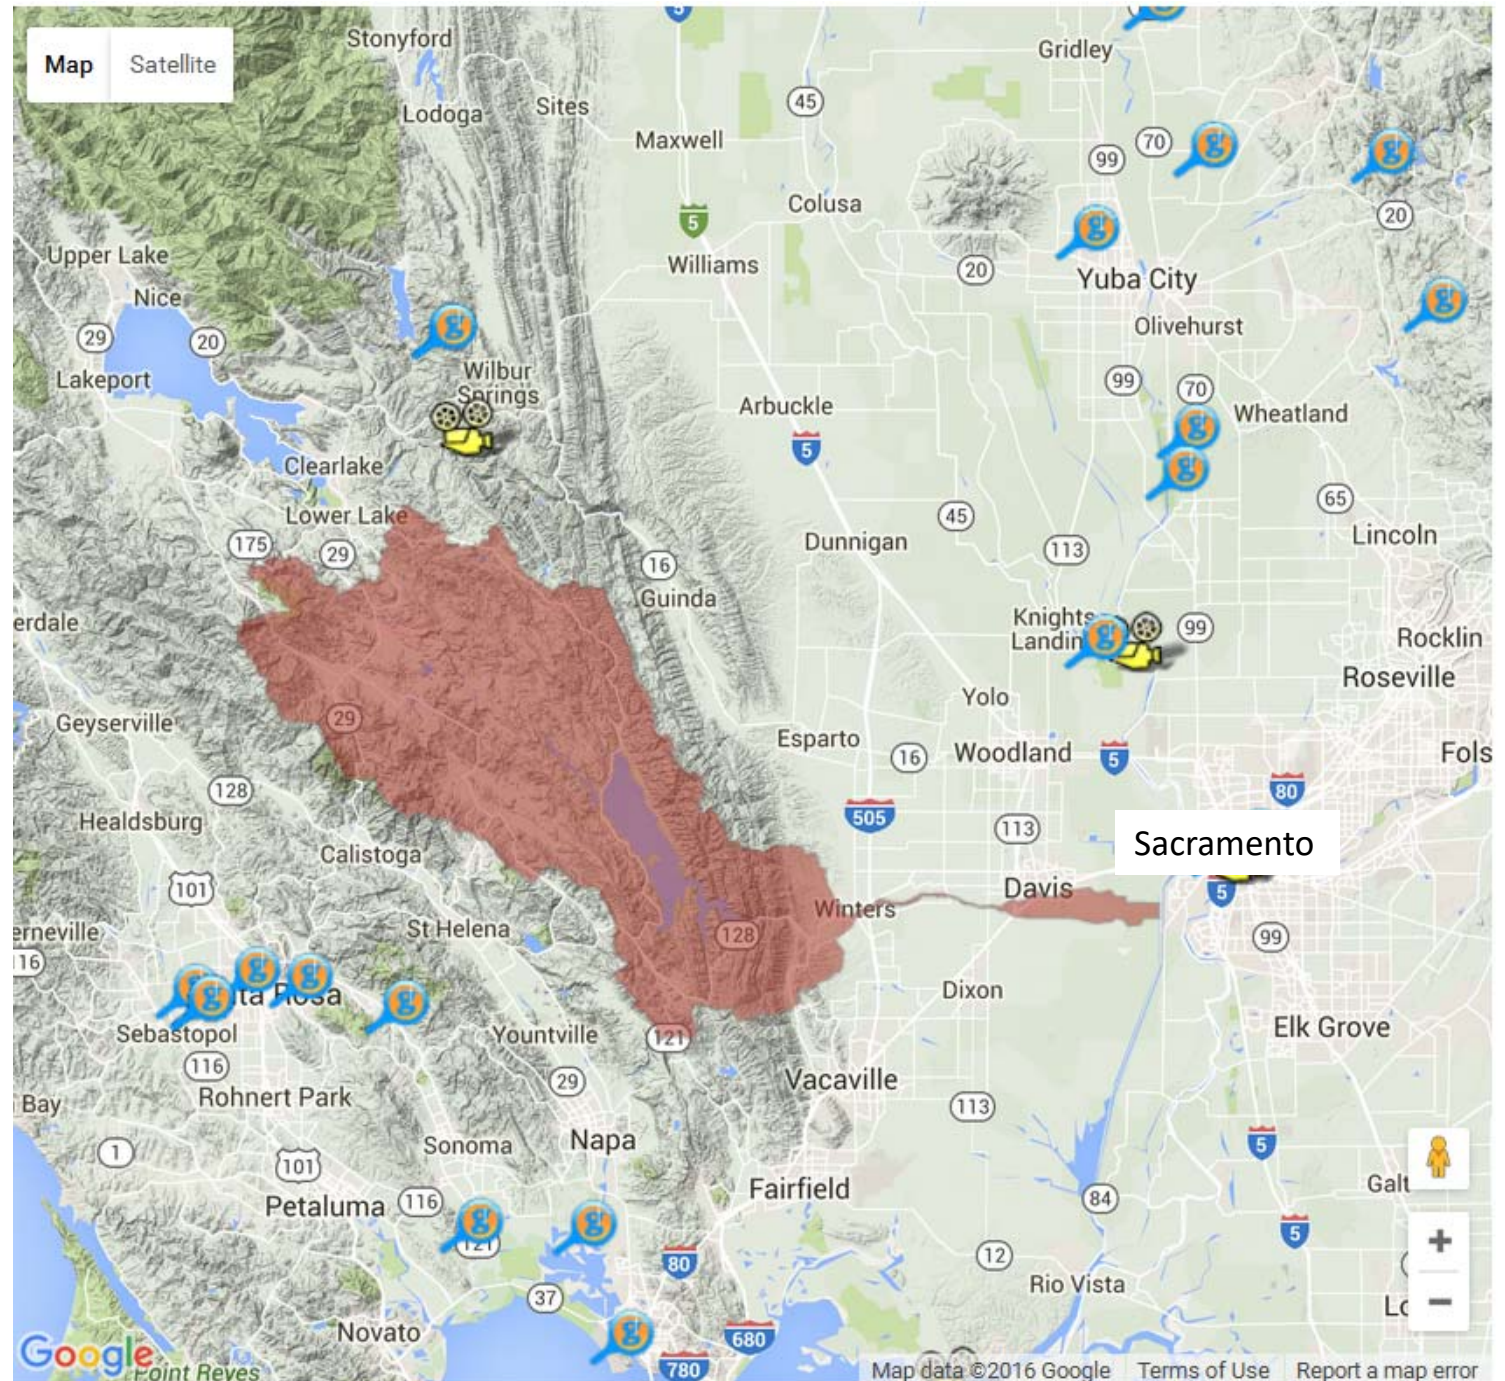

Outline

- Putah Creek: watershed context
- Floodplain analysis
 - Recruitment box theory
- Methods
 - Relative elevation and HAR concepts
 - GPS data collection
- Results
 - Sacramento River
 - Putah Creek
- Vegetation analysis
 - Cottonwood and elderberry examples
- Future work

Recruitment box theory

- Explains the process of cottonwood tree establishment on floodplain surfaces, such as point bars
- First key concept: Timing between the falling limb of the hydrograph and release of cottonwood tree seed
- Second key concept: A suitable band of bank elevation on the point bar above summer base flow

See Mahoney and Rood (1998), *Wetlands* 18(4):634-645

Figure 1. The daily hydrograph for the Oldman River, at Lethbridge, Alberta, for 1922, prior to the construction of major dams upstream. Roman numerals represent important components relevant to cottonwood seedlings recruitment: (I) high flows to drive geomorphological processes that create suitable moist and barren nursery sites, (II) falling flows to expose the nursery sites, (III) gradual flow decline after germination that permits the growing roots to maintain contact with the receding moisture zone, (IV) sufficient flows through the hot and dry period of mid- to late summer, and (V) sufficient flows in late summer and autumn to provide the seedlings with a favorable water balance to withstand the winter.

Mahoney and Rood 1998

Figure 3. The 'Recruitment Box,' a zone defined in elevation and time in which riparian cottonwood seedlings are likely to become successfully established if stream flow patterns are favorable. The graphs represent phenology of components (top), survivable rate of stage decline (middle), and a hydrograph that satisfies requirements for seedling establishment (bottom).

The graphs represent phenology of components (top), survivable rate of stage decline (middle), and a hydrograph that satisfies requirements for seedling establishment (bottom).

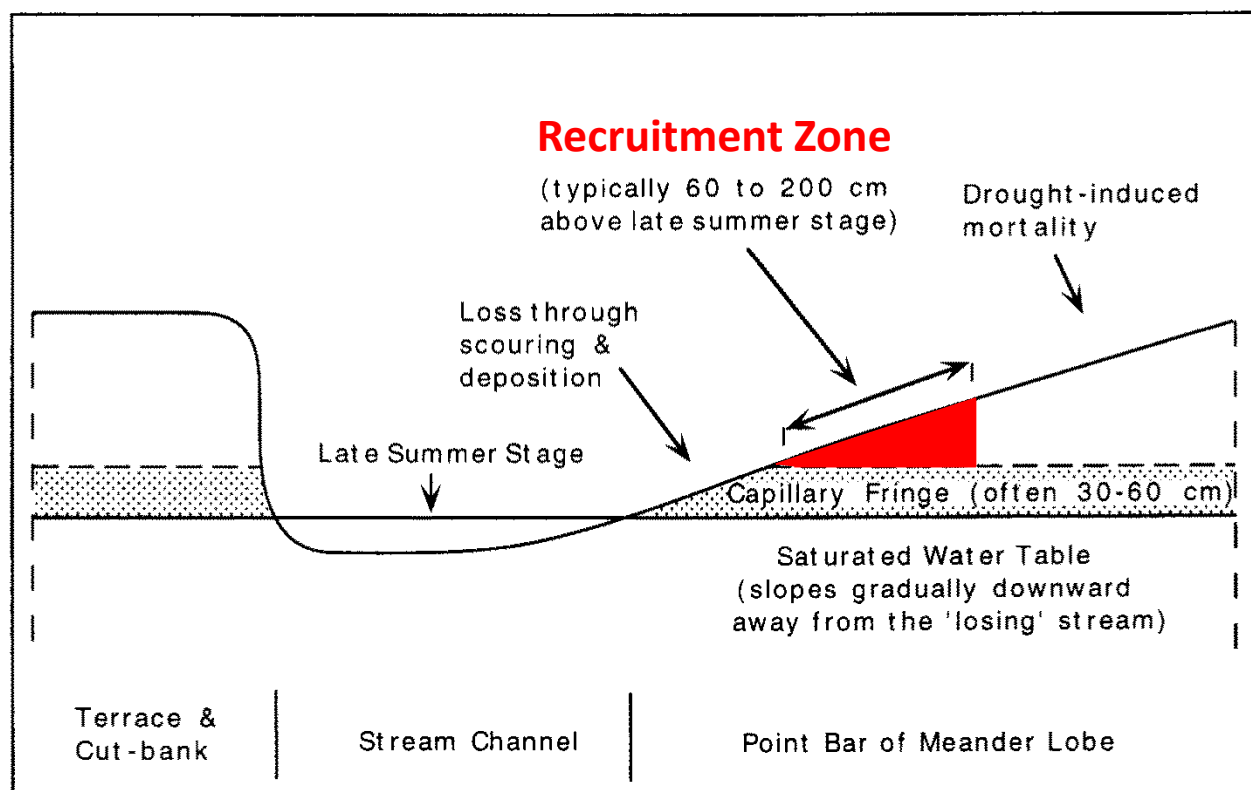

Figure 4. Cross section of a stream and riparian zone at the point bar of a meander lobe, showing the riparian water table, the capillary fringe, and the suitable band for cottonwood establishment and survival.

“Relative elevation” concept (Greco et al. 2008)
or
“Height-above-river (HAR)” (Dilts 2010)

Figure 2. The relative elevation concept. The base-flow or average low-flow conditions water surface elevation of the channel (e.g. 54 m, shown as a dashed line) using mean sea level (MSL) as the datum for the elevation units is used as a local datum to subtract the local land elevation surface value from (e.g. 60 m at MSL, as depicted), in order to derive land elevation values relative to the local datum (e.g. 6 m, as shown in quotes). The relative elevation of the water surface of the main channel has a calculated value of zero (m), as shown in quotes, along its entire length.

A de-trending process of a topographic map

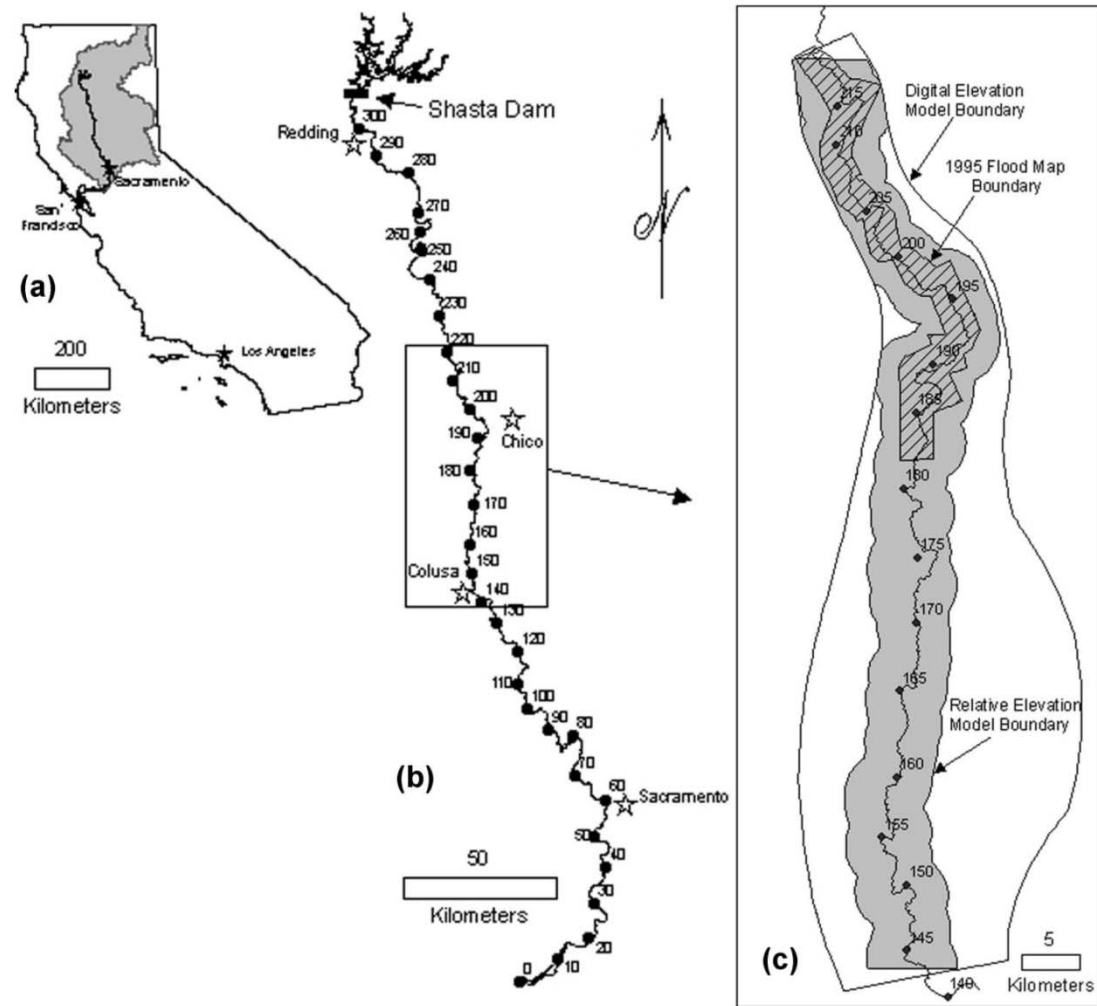

Figure 3. Location maps of the Sacramento River and the study areas. a) The Sacramento River and its watershed (grey tone) within the state of California. b) The Sacramento River is shown in 10-mile increments from river-mile 0 in the San Francisco Bay Delta to river-mile 300 near Shasta Dam. c) Study area boundaries: the raster digital elevation model boundary (no fill), the relative elevation model boundary (grey tone), and the observed 1995 flood map boundary (hatched pattern). River-miles are shown in five-mile increments.

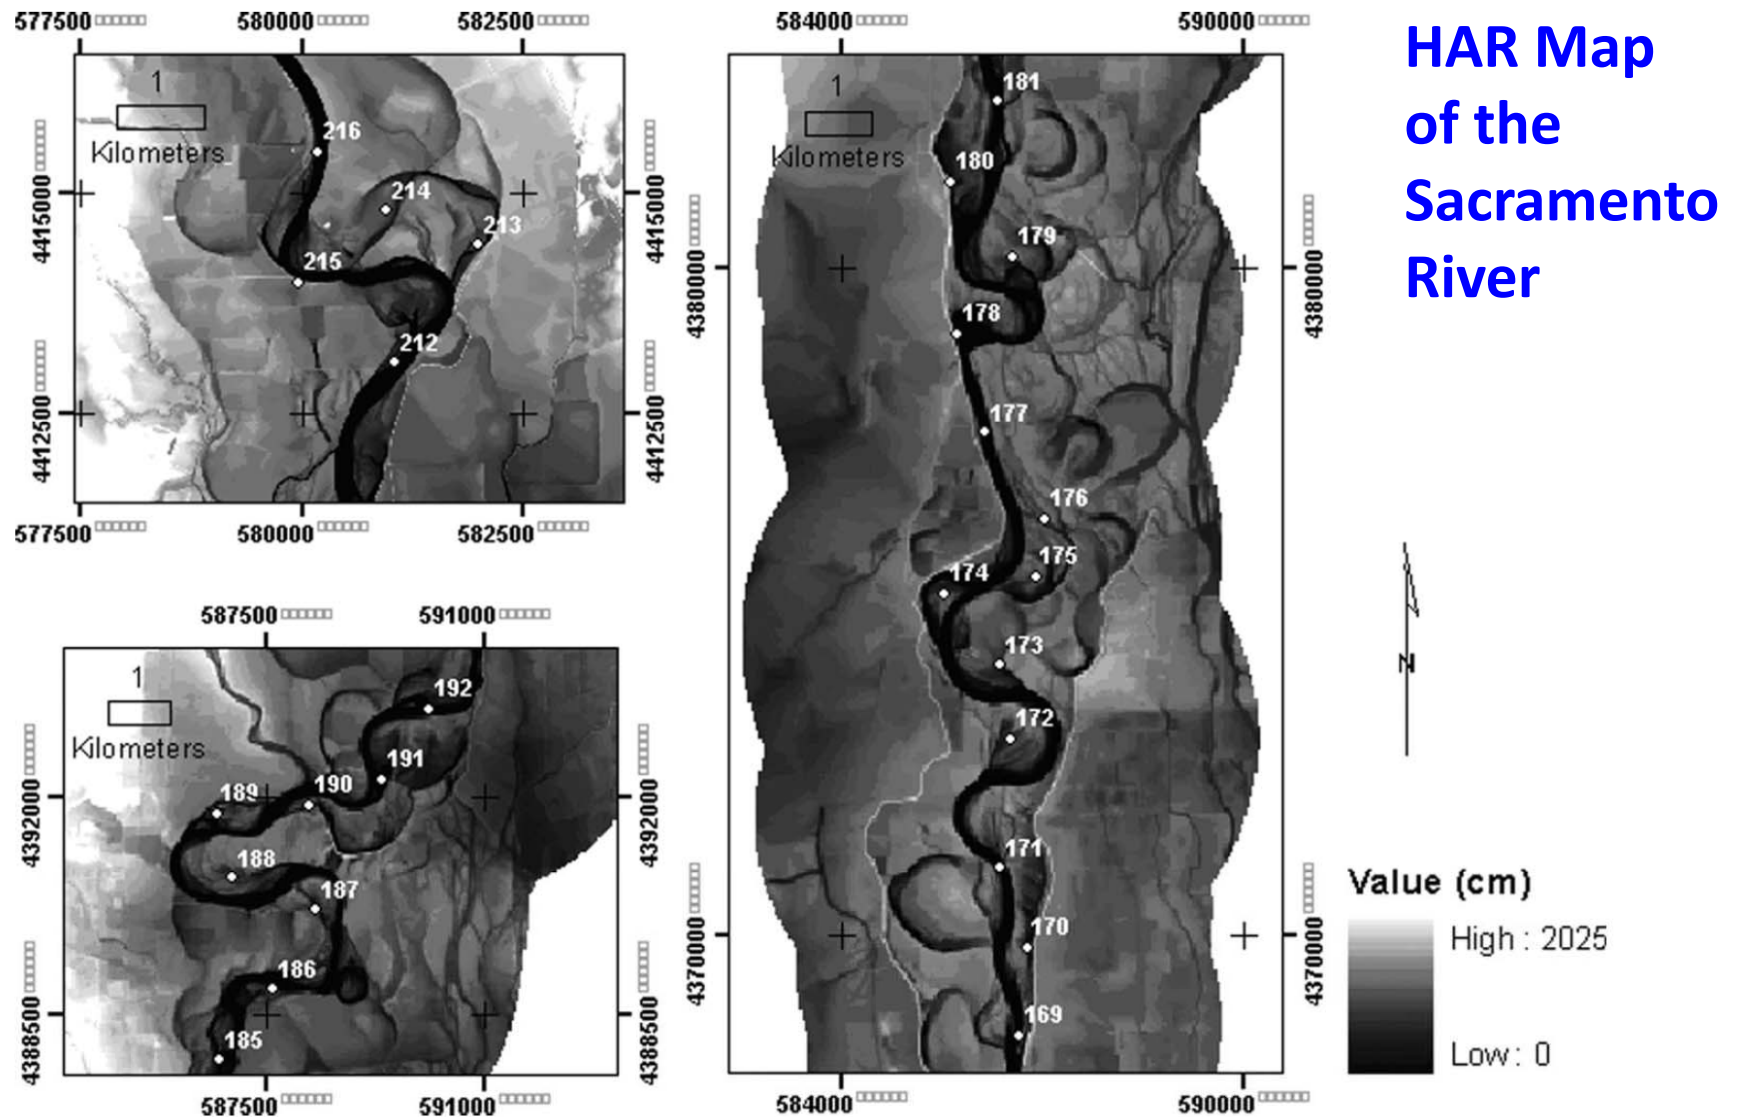

Figure 4. Example relative elevation surface maps of three areas within the study reach of the Sacramento River, USA. River-miles are shown as white points and text. Tick marks show the UTM coordinate system (zone 10, NAD27).

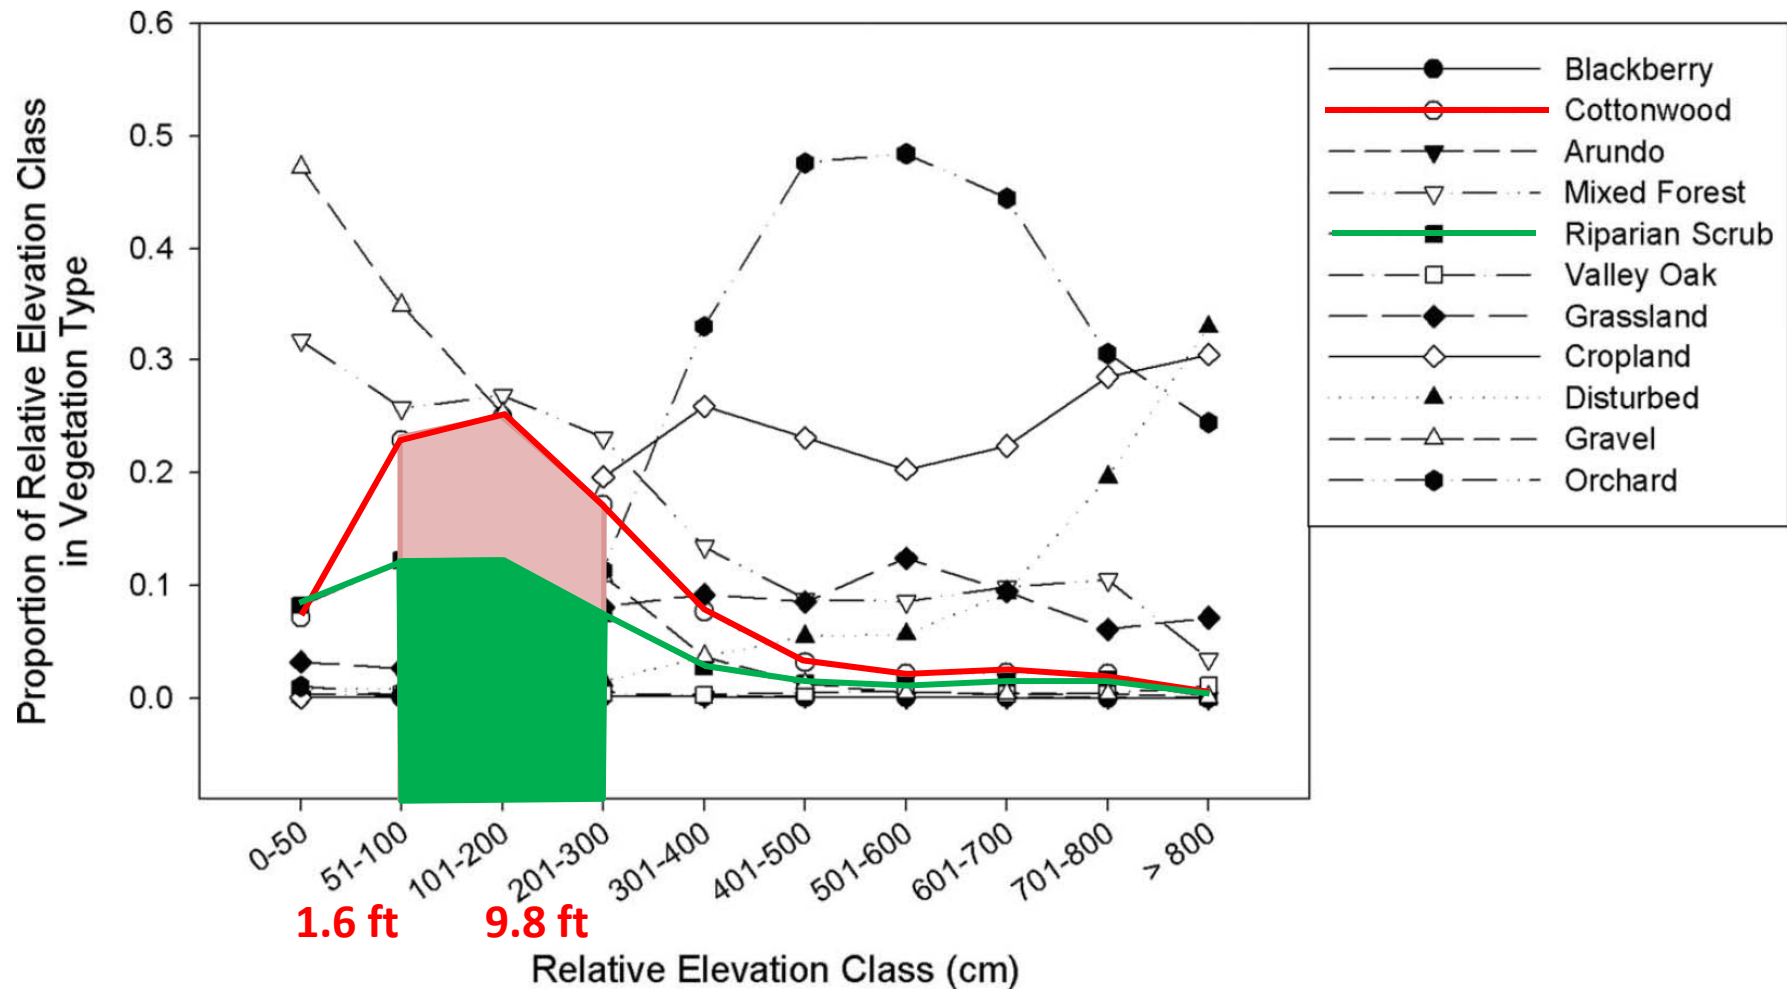

Figure 9. The proportion of the total area of each relative elevation class covered by each vegetation community and land cover type. Note the proportions sum to 1.0 for each relative elevation class.

“The Effective Recruitment Box” = observed patterns of recruitment

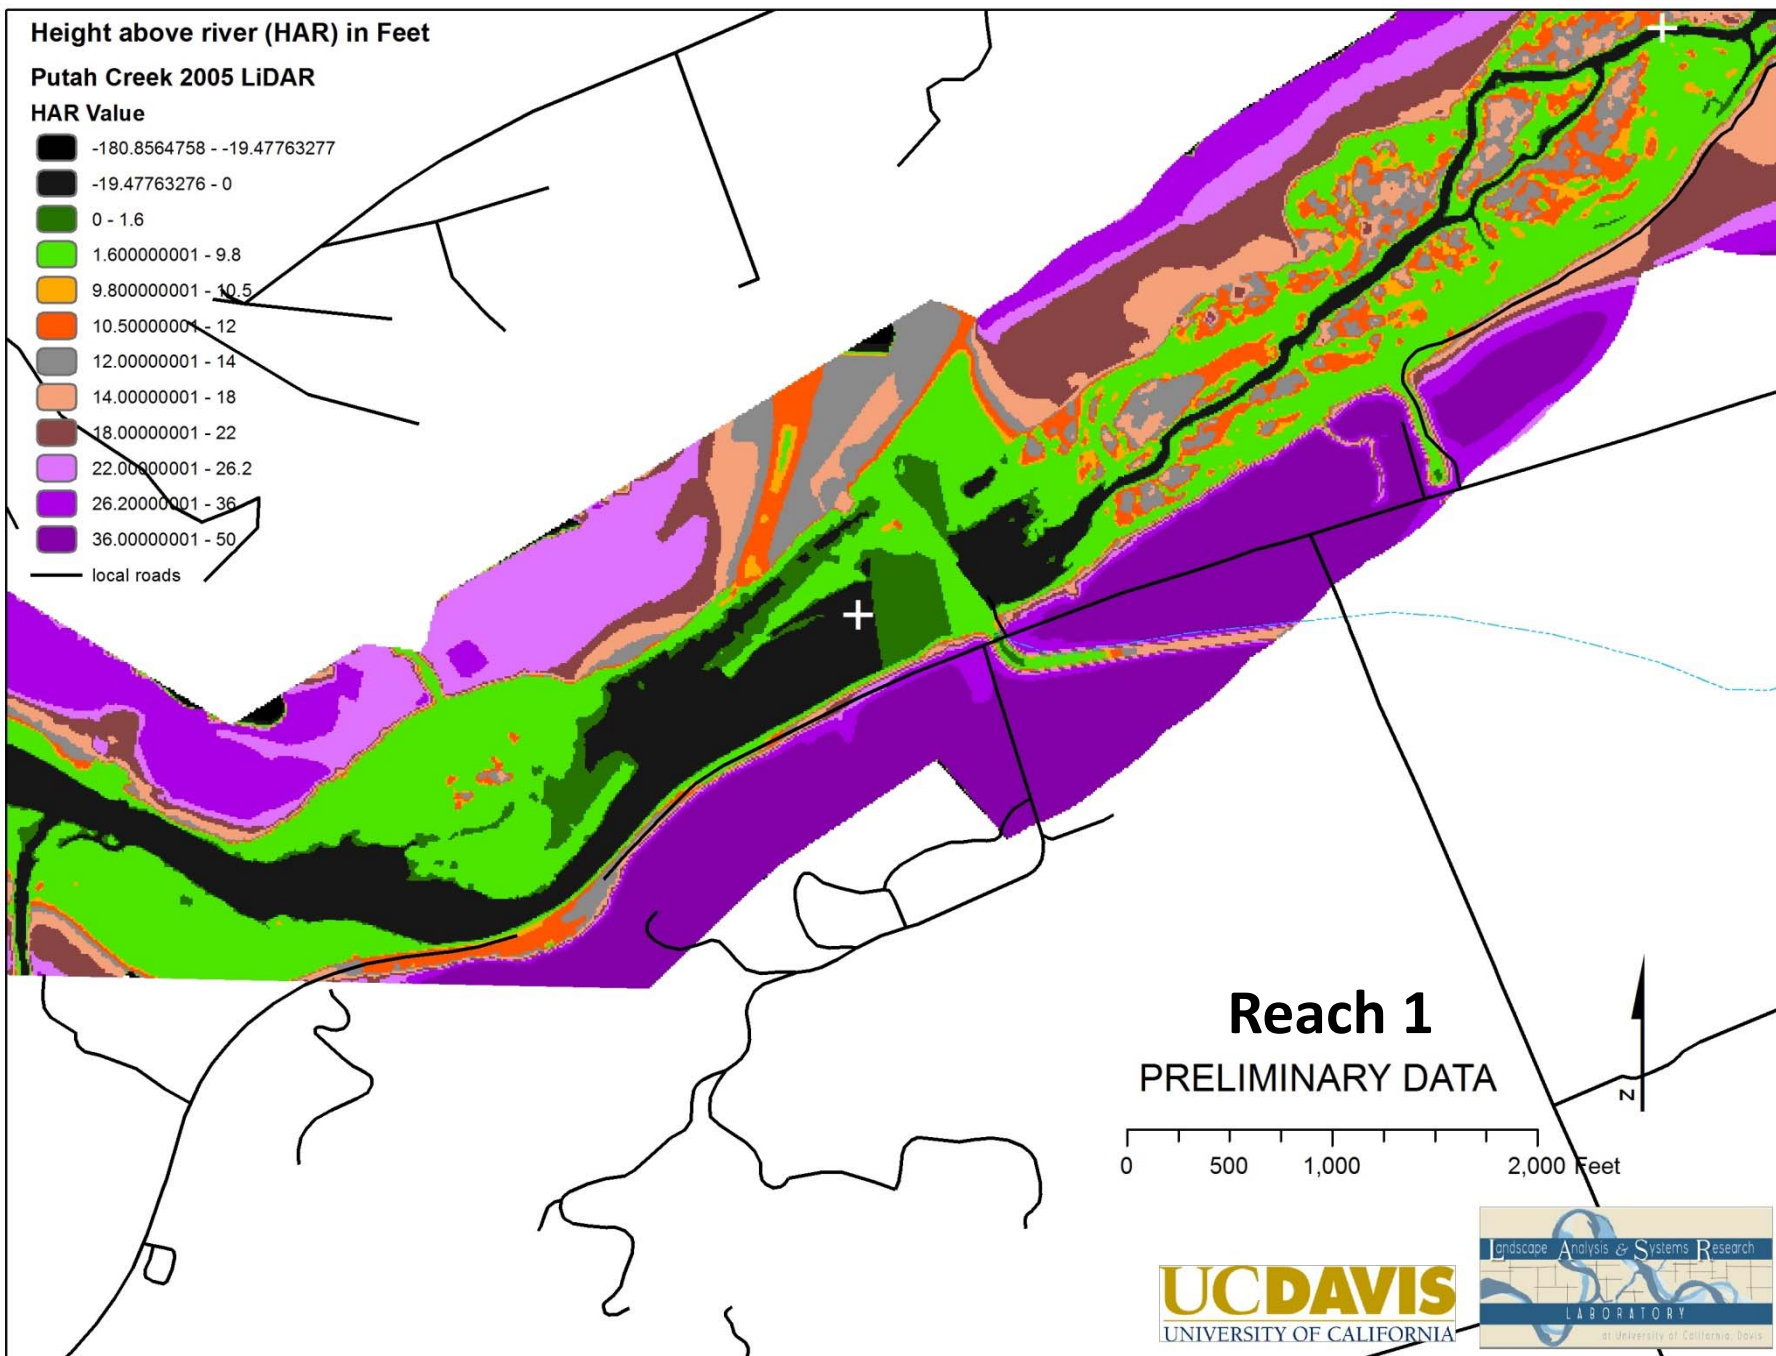

HAR Map of Putah Creek

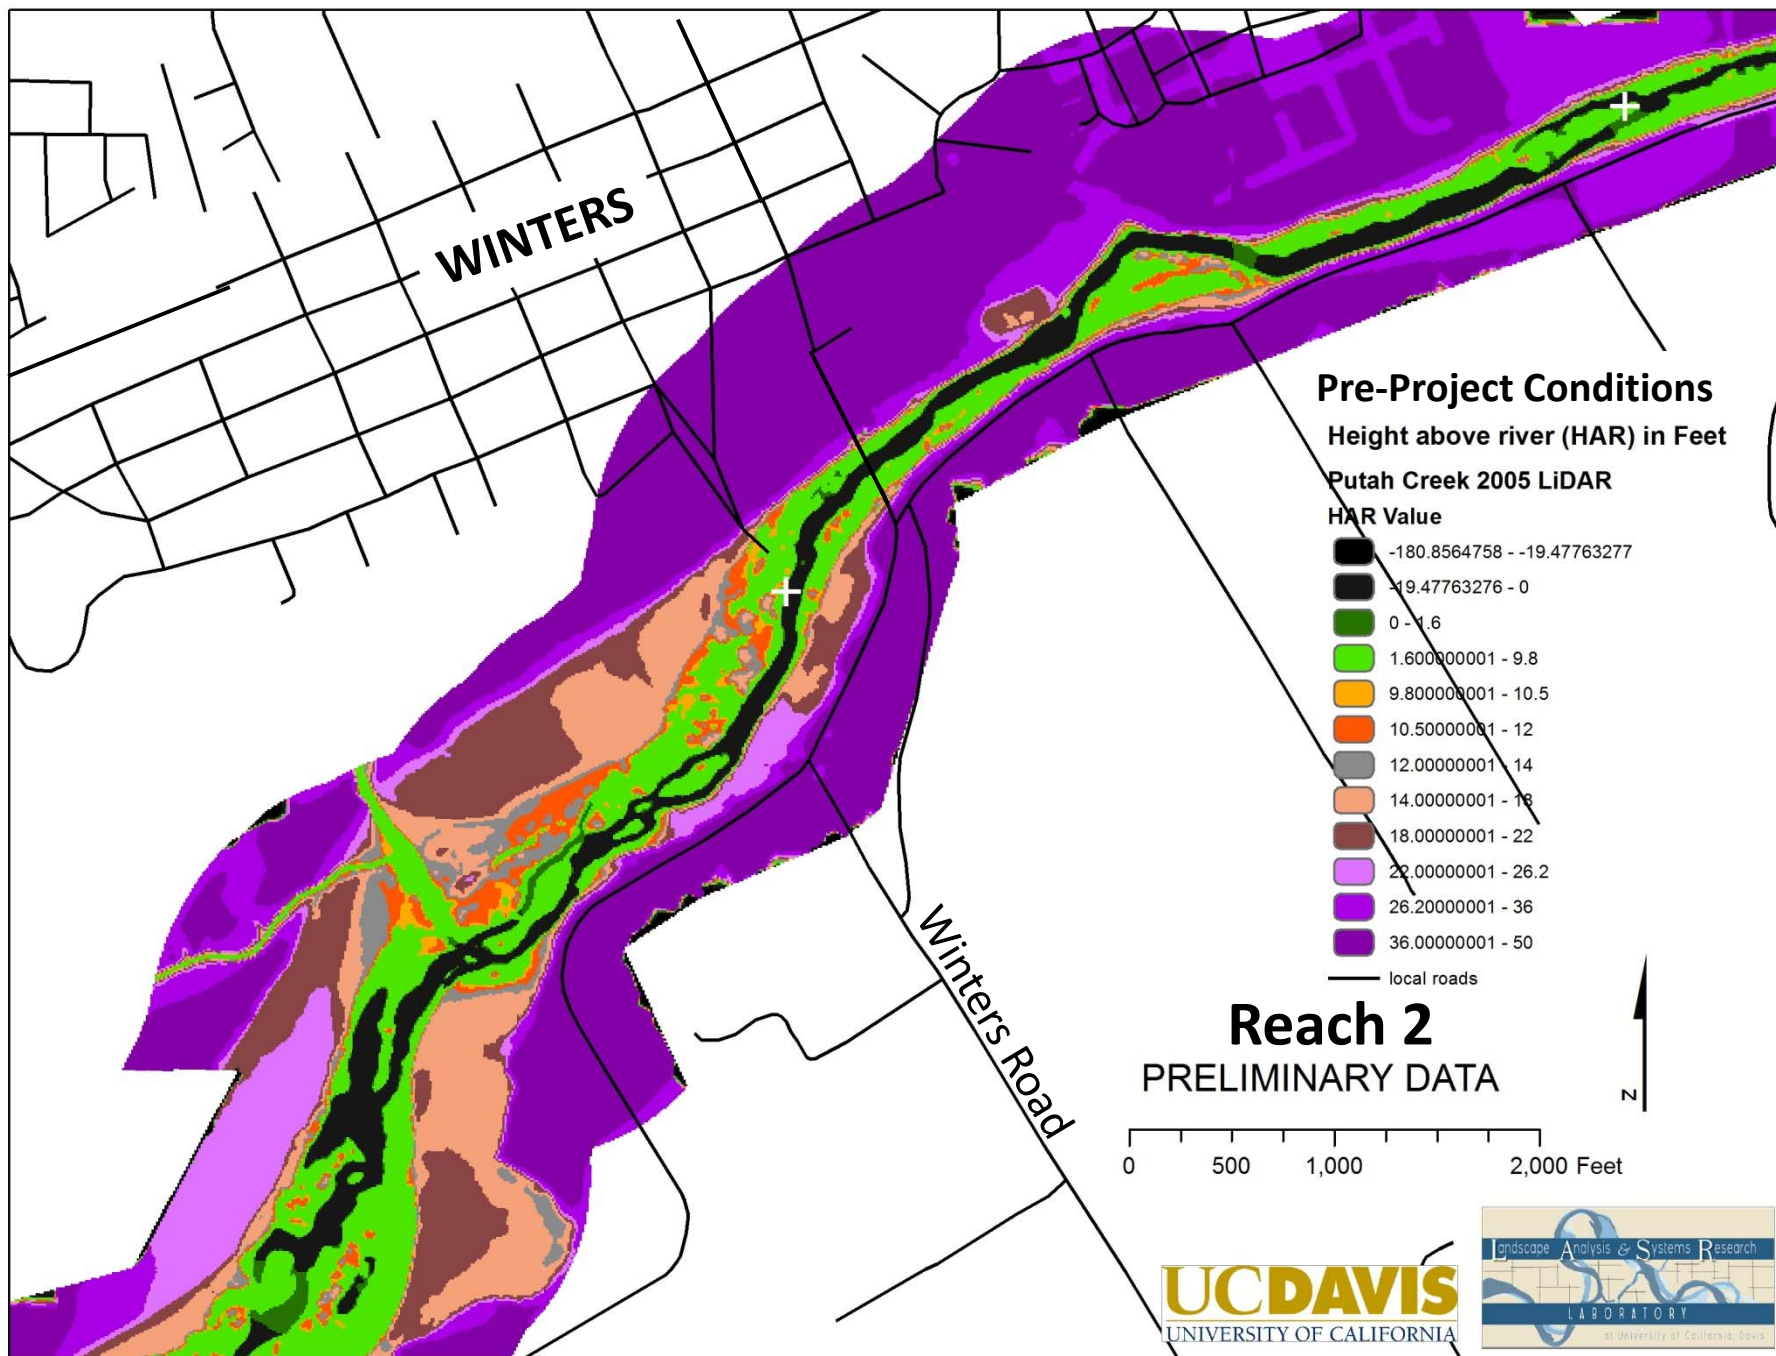

- Based on 2005 LiDAR data and a water surface mapped by JSA
 - Water surface matches well to partially mapped LiDAR water surface
 - Estimated flow: 20 cfs releases (5 cfs at I-80)
- Used the HAR algorithm in the “Riparian” toolbox in “Topographic Tools” for ArcGIS (v10.3)
- Results presented from upstream (at Putah Diversion Dam) to downstream (the Putah Creek Sinks)
- 8 example reach maps

HAR Distribution of *Sambucus mexicana* (elderberry) on Putah Creek (n = 437)

Elderberry HAR Distribution	
Mean	27.28301574
Standard Error	0.474715093
Median	30.61288452
Mode	21.40689087
Standard Deviation	9.923703001
Sample Variance	98.47988125
Kurtosis	-0.529376216
Skewness	-0.689626404
Range	46.91171265
Minimum	0.879882813
Maximum	47.79159546
Sum	11922.67788
Count	437
Confidence Level(95.0%)	0.93301443

Elderberry has a mean relative elevation (or height above river, HAR) of **27 ft** with a std dev of 10 ft, meaning 67% of all mapped elderberry is distributed between **17 ft and 37 ft** above the channel's low flow (the “**effective recruitment box**”).

➤ it is predominantly an upland species

Future Work

- Offset DGPS data collection of other tree species to estimate HAR distribution (effective recruitment box):
 - Cottonwood (*Populus fremontii*)
 - Various willow species (*Salix* spp.)
 - Walnut (*Juglans* spp.)
 - Valley oak (*Quercus lobata*)
- Further refinement of the HAR model
